

Marriage Timing Discrete Time Event History Analysis Code for the ChitwanABM

Author: Alex Zvoleff

Email: azvoleff@mail.sdsu.edu

Date: July, 2012

Follows analysis of Yabiku (2006):

Yabiku, S. T. 2006. Land use and marriage timing in Nepal. Population & Environment 27 (5):445–461.

Uses the `glmer` function from the R `glmer` package to conduct a multilevel discrete-time event history analysis of marriage timing using the monthly Chitwan Valley Family Study (CVFS) household registry data.

```
library(ggplot2)
library(lme4)
library(arm) # for se.coef, se.fixef
# theme_update(theme_grey(base_size=10))
theme_update(theme_bw(base_size = 10))
# update_geom_defaults('point', aes(size=2)) update_geom_defaults('line',
# aes(size=.75))

load("data/marriage_data-longformat-up_to_month_90.Rdata")

# Drop 'other' ethnicity for consistency with Massey et al. (2010)
marit_long <- marat_long[!(marit_long$ethnic == "Other"), ]
marit_long$ethnic <- factor(marit_long$ethnic)

# To stabilize numerical algorithm (to avoid 'false convergence' error in
# glmer), try categorizing age by decade, converting time to decades and
# try adding a continuous age variable in decades. This makes the betas on
# age and time larger and helps stabilizes the optimization algorithm.
marit_long$timeyears <- marat_long$time/12
marit_long$agedecades <- marat_long$age/10

# Create a monthly factor that can be used to remove the effects of
# seasonal variation in marriage rates
marit_long$month <- factor(marit_long$time%%12 + 1)
```

Basic Statistics

Total number of person-month records: 46000. Now look at a table of how those records are distributed (0 being unmarried, 1 being married).

```
table(marit_long$marit, exclude = NULL)
```

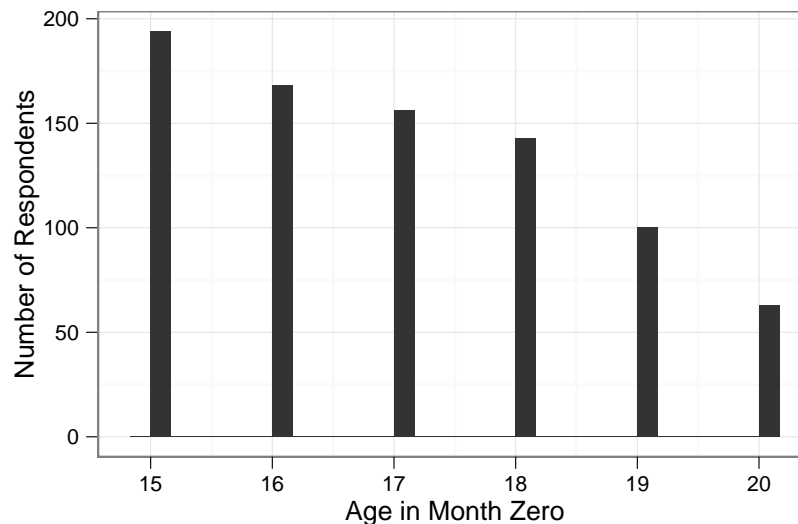

```
##
##      0      1  <NA>
## 45513   487      0
```

Basic Statistics

Make a quick plot of the age distribution of the sample in the first month of data collection (when all are unmarried)

```
ggplot(age, geom = "bar", data = marit_long[marit_long$time == 1,
], xlab = "Age in Month Zero", ylab = "Number of Respondents")
```

```
## stat_bin: binwidth defaulted to range/30. Use 'binwidth = x' to adjust
## this.
```

Age distribution of sample in initial month of data collection

Also plot the age at marriage

Note

This sample only includes 90 months of data from people who were 15-20 in 1996, so the max possible age at marriage in this sample is 27.5. When tested with a sample including those from age 15-90, the number of marriages by age is:

```
>table(marit_long[marit_long$marit==1,]$age)
15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 34 35 41
1  12 26 53 71 69 66 79 56 54 38 29 17  8 12  4  4  1  1  1  1
```

Given that there are so few marriages of those above age 30, the assumption is made in the ChitwanABM that if you are not married by age 30, you will not be getting married. Hence there is a "maximum_marriage_age" parameter in the model

```
ggplot(age, geom = "bar", data = marit_long[marit_long$marit == 1,
], xlab = "Age", ylab = "Number of Marriages")
```

Basic Statistics

```
## stat_bin: binwidth defaulted to range/30. Use 'binwidth = x' to adjust  
## this.
```

Age at first marriage

```
table(marit_long[marit_long$marit == 1, ]$age)
```

```
##  
## 15 16 17 18 19 20 21 22 23 24 25 26 27  
##  1 12 26 53 71 69 65 70 43 36 24 14  3
```

Note that marriage is seasonal, so include a dummy variables for each month later on in the models:

```
qplot(month, geom = "bar", data = marit_long[marit_long$marit ==  
1, ], xlab = "Month", ylab = "Number of Marriages")
```

Basic Statistics

plot of chunk marriages-month-hist

Check cross tabs of marit with the categorical predictors:

```
xtabs(~marit_long$age + marit_long$marit, exclude = NULL)
```

```
##           marit_long$marit
## marit_long$age    0     1
##           15  580     1
##           16 2721    12

##
```

Now make a quick plot of a histogram of $\log(\text{percent agricultural vegetation} + 1)$, for the first month:

```
qplot(marit_long[marit_long$time == 1, ]$interp_logpercagveg, geom = "histogram")
```

Discrete-time Event History Models

```
## stat_bin: binwidth defaulted to range/30. Use 'binwidth = x' to adjust  
## this.
```

Discrete-time Event History Models

Fixed effect model

Do two fixed effects models. First do a GLM with age in years, then a GLM with age in decades. Yabiku (2006) presents results with age in years, but the `glmer` optimization routine wouldn't converge unless age was rescaled to decades. So do a GLM with age in years for comparison with the Yabiku (2006) results, but use age in decades for the final model to be included in the ABM.

```
marr_fixed <- glm(marit ~ ethnic + gender + age + I(age^2) + interp_logpercagveg +  
  schooling_yrs + month, data = marit_long, family = binomial)  
save(marr_fixed, file = "models/marr_fixed.Rdata")  
summary(marr_fixed)
```

```
